

Module 4: Multi-account deployments

In this module, we will go through the process of deploying environments and services to different accounts. Maintaining separate AWS accounts for different deployment stages is a standard practice for organizations. It helps developers limit the blast radius in case of failure when deploying updates to an application, and provides for more resilient and distributed systems.

If you want to test multi-account you will need more than one AWS account. If you are at a an AWS hosted event, you will need to share accounts with another attendee. If you are running on your own you will need to create a new account within your organization in AWS Organizations (click [here](#)  for more information).
